Introduction

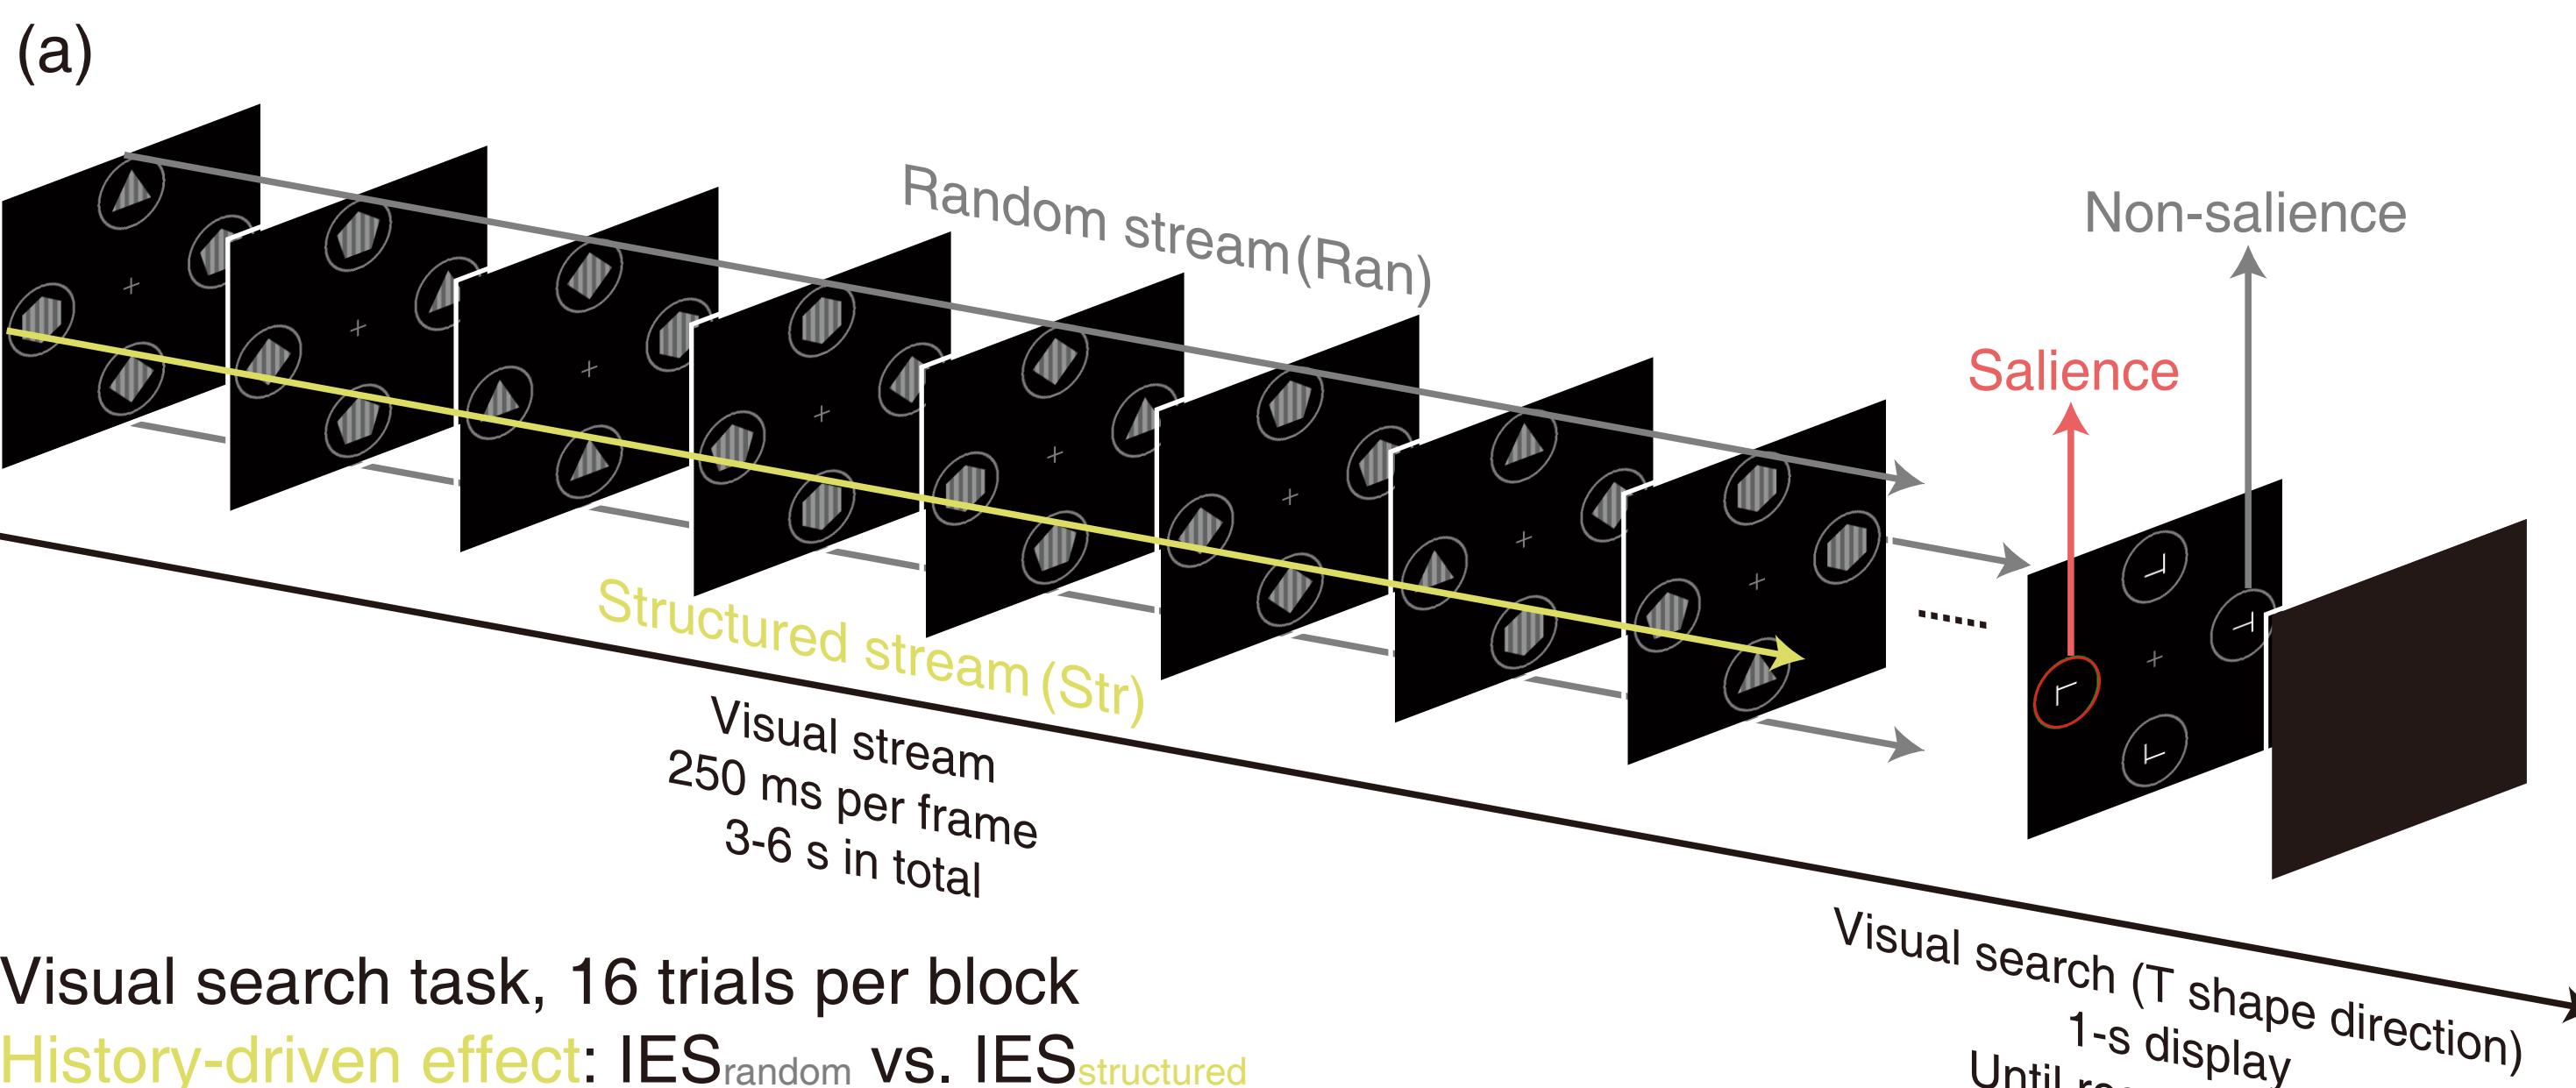

Selection history built on statistical learning has been proposed as a third factor guiding attention, parallel to goal-driven and stimulus-driven selections [1-3].

Within this framework, how history-driven factors (e.g., statistical regularities) interact with stimulus-driven effects (e.g., physical salience) to influence attentional selection remain largely unclear.

Thus, the current research investigated the mutual impacts between regularity and stimulus salience on attentional selection (Experiment 1) and the way these attentional effects interact to shape attentional priority computation (Experiment 2).

Procedure

Experiment 1a & 1b: Mutual influences

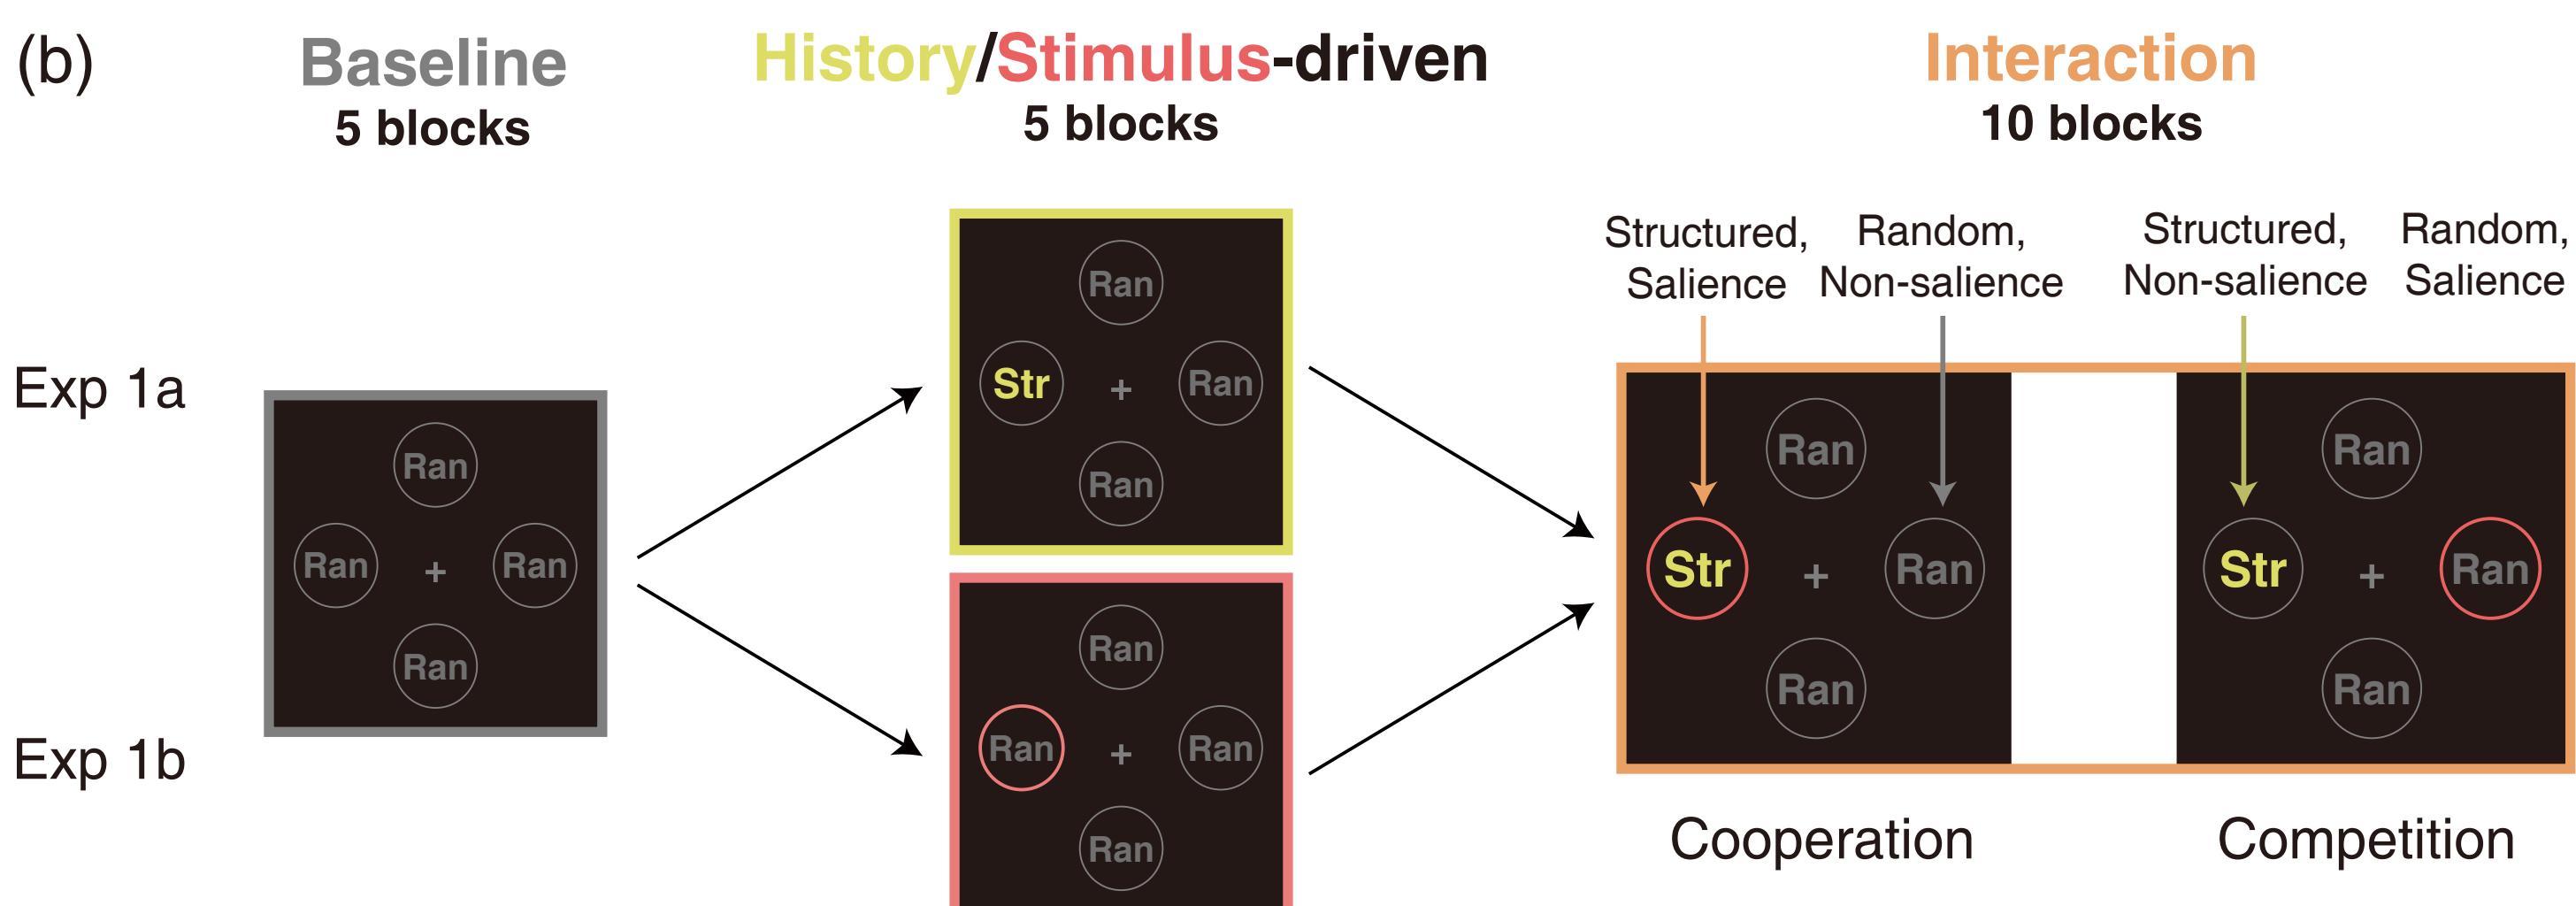

Visual search task, 16 trials per block

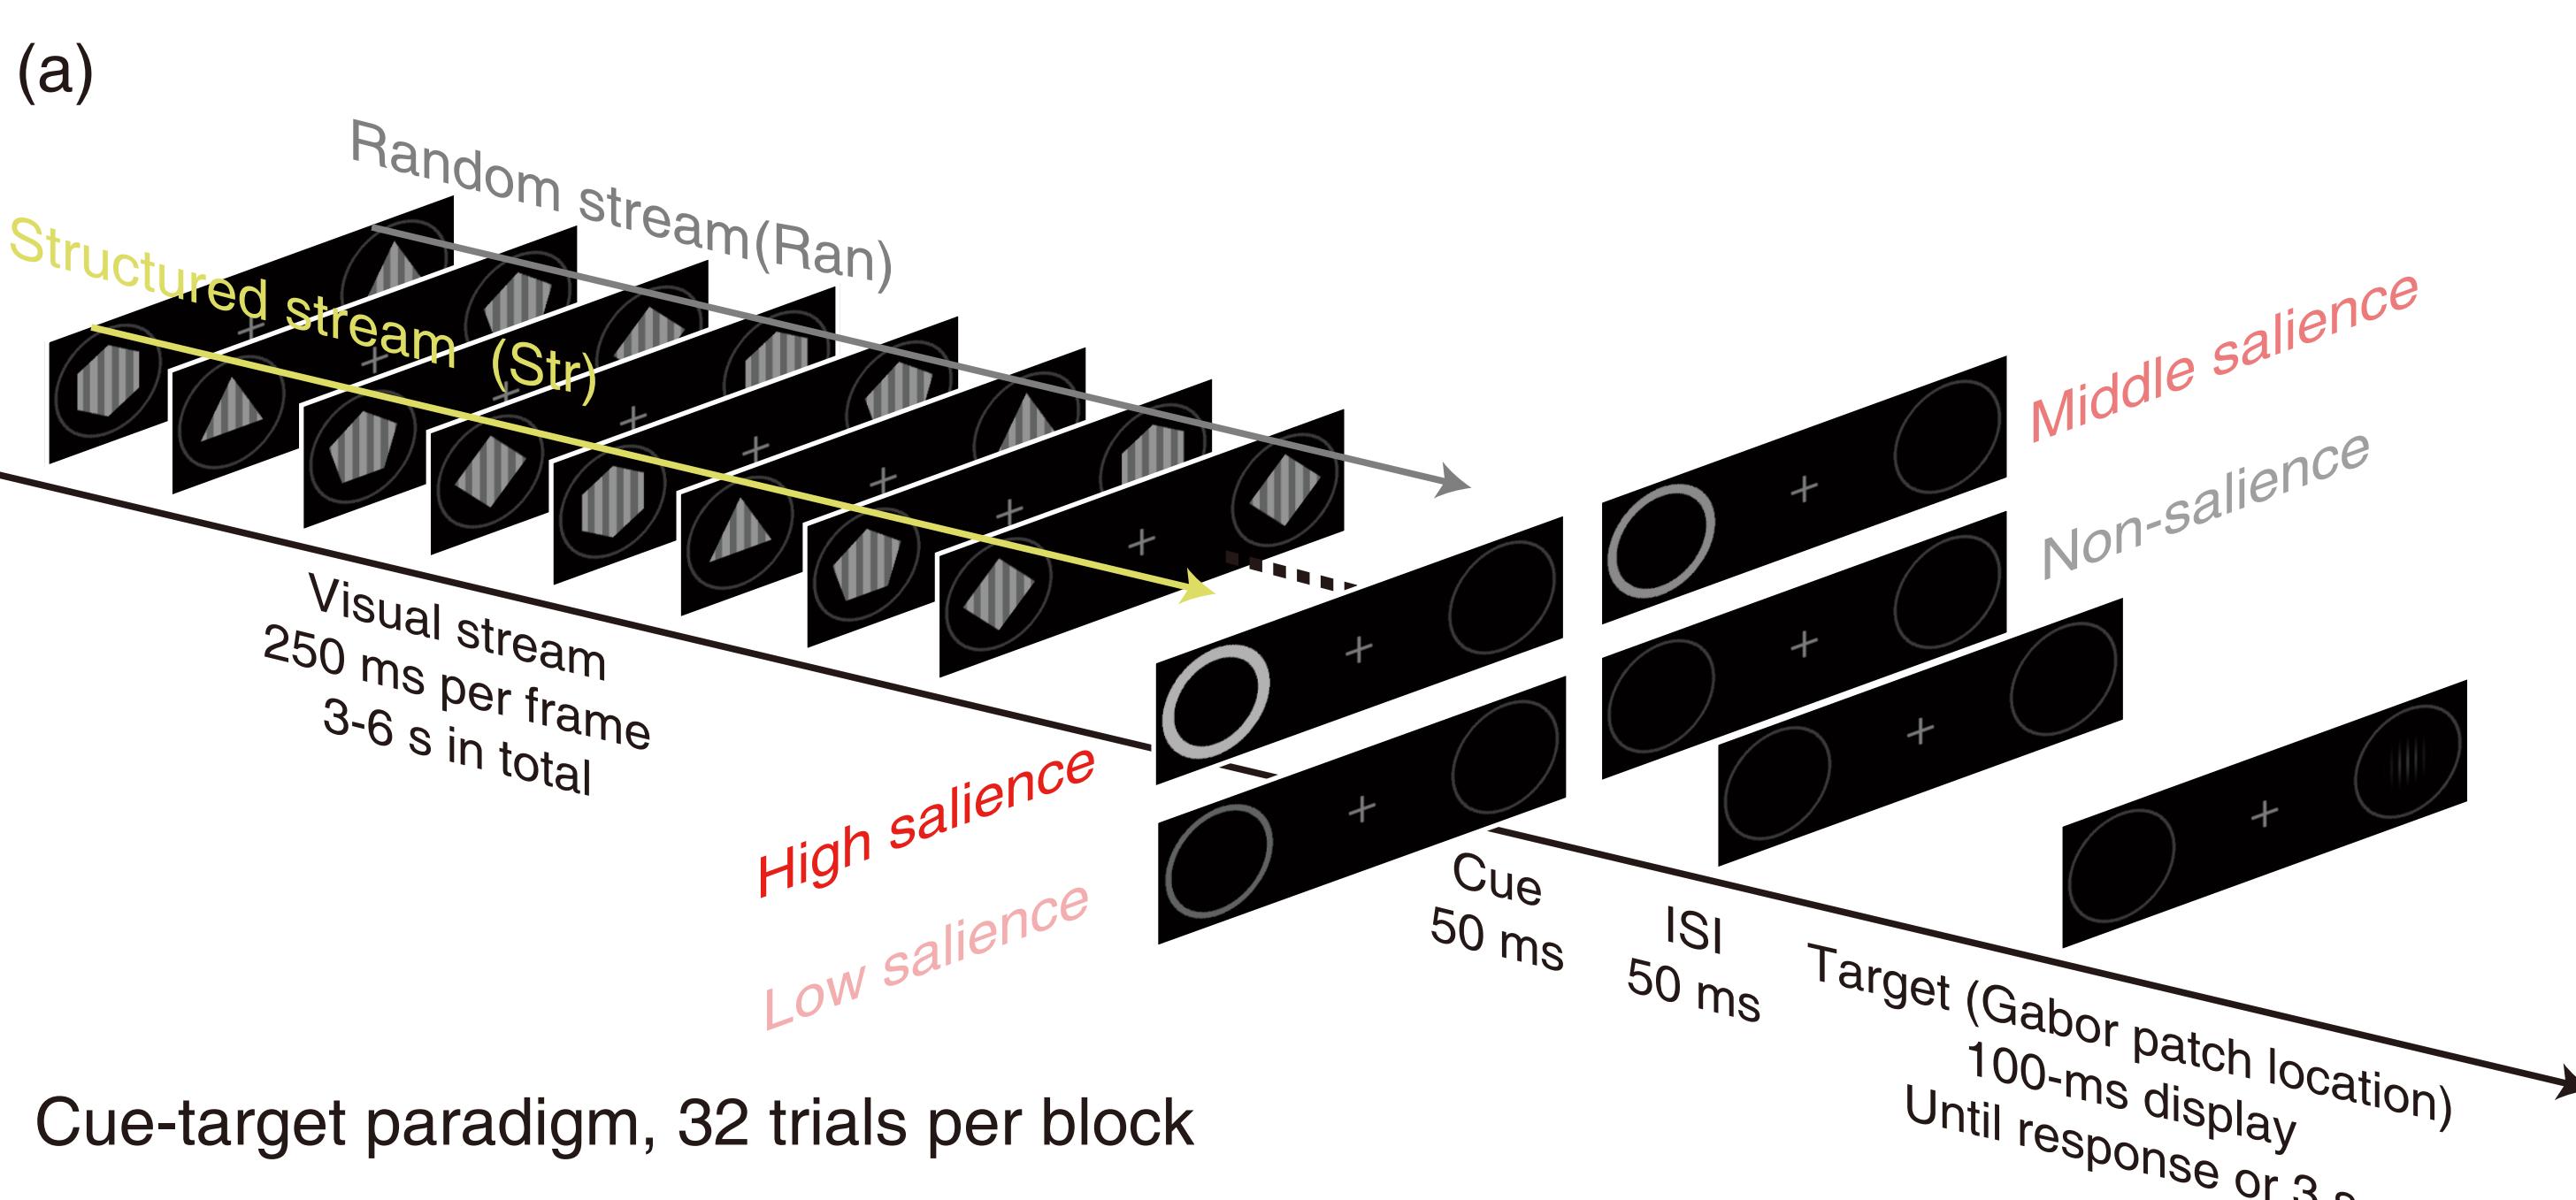

History-driven effect: $IES_{\text{random}} \text{ vs. } IES_{\text{structured}}$

Stimulus-driven effect: $IES_{\text{non-salience}} \text{ vs. } IES_{\text{salience}}$

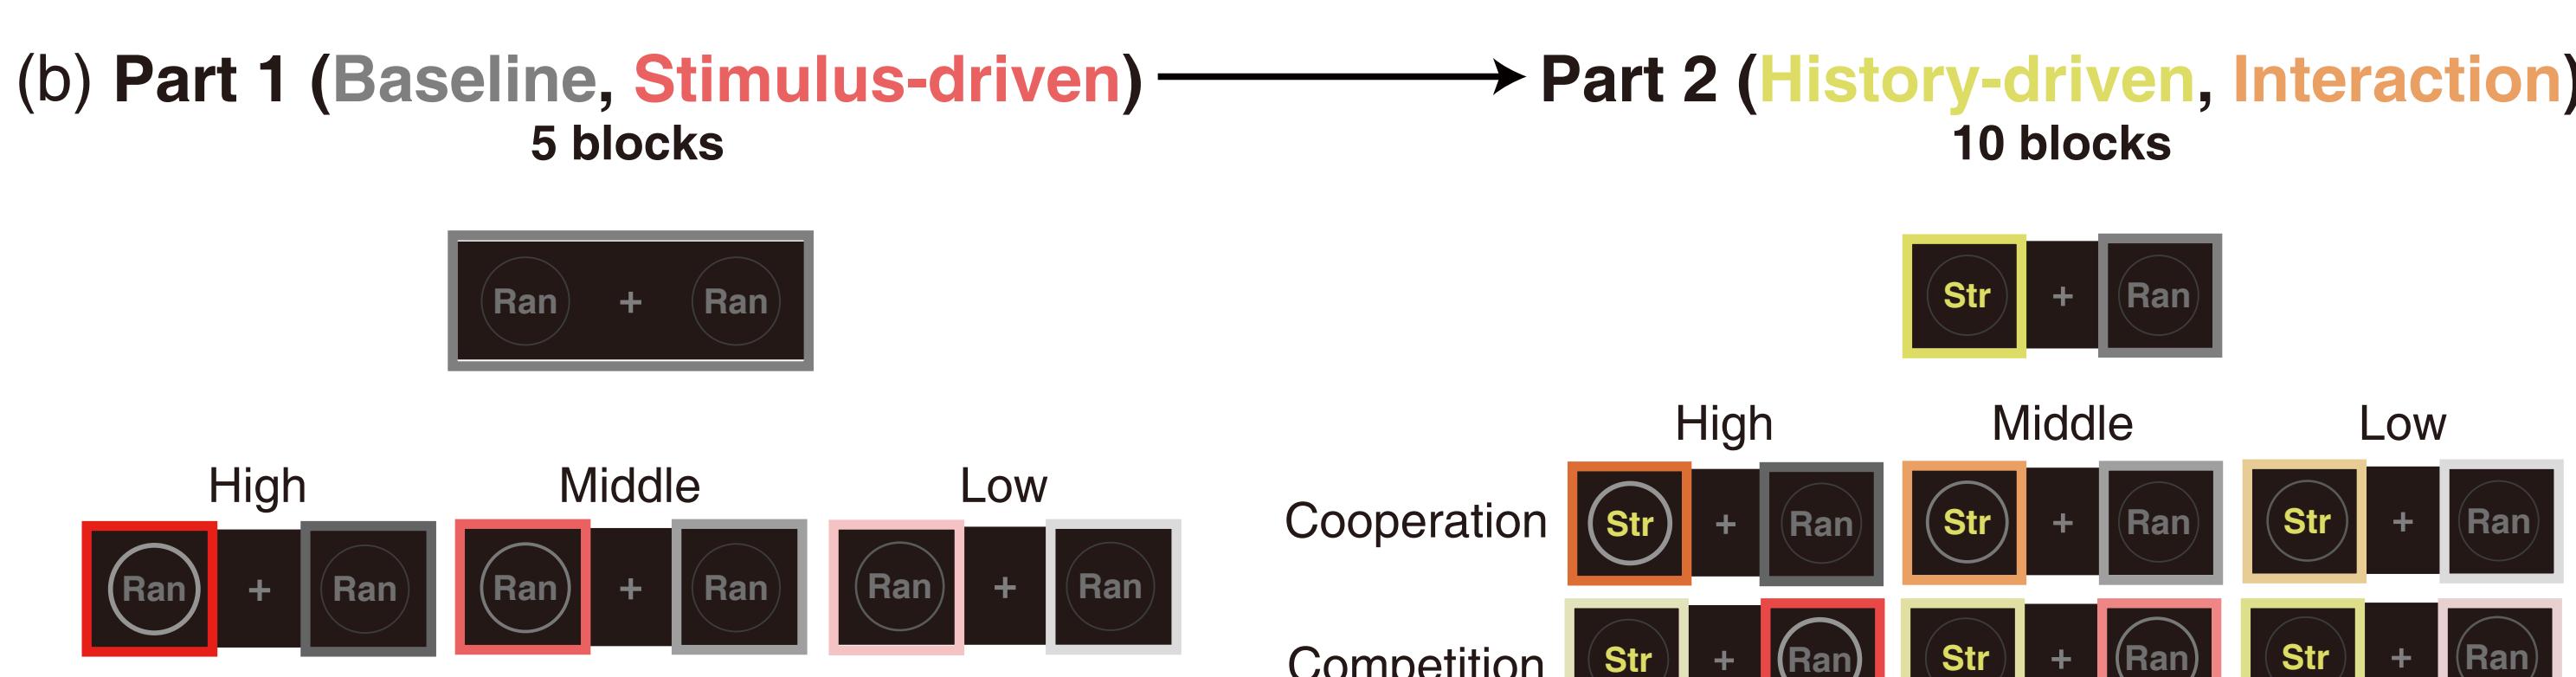

$IES = RT/ACC$

Experiment 2: Interaction mode

Cue-target paradigm, 32 trials per block

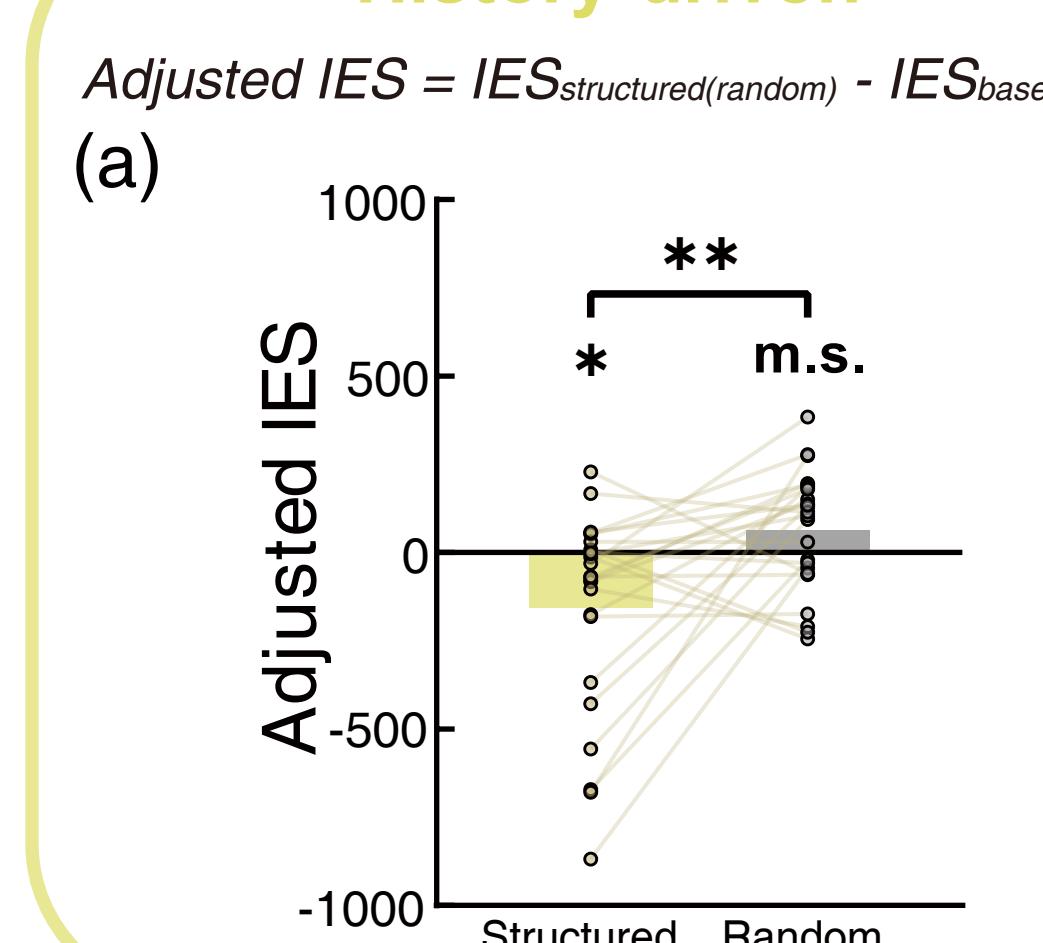

Conclusion

- Statistical regularity and physical salience jointly but independently guide attentional prioritization in an additive manner.
- These results provide novel insights into how selection history and present information work in tandem to shape attentional priority computation.

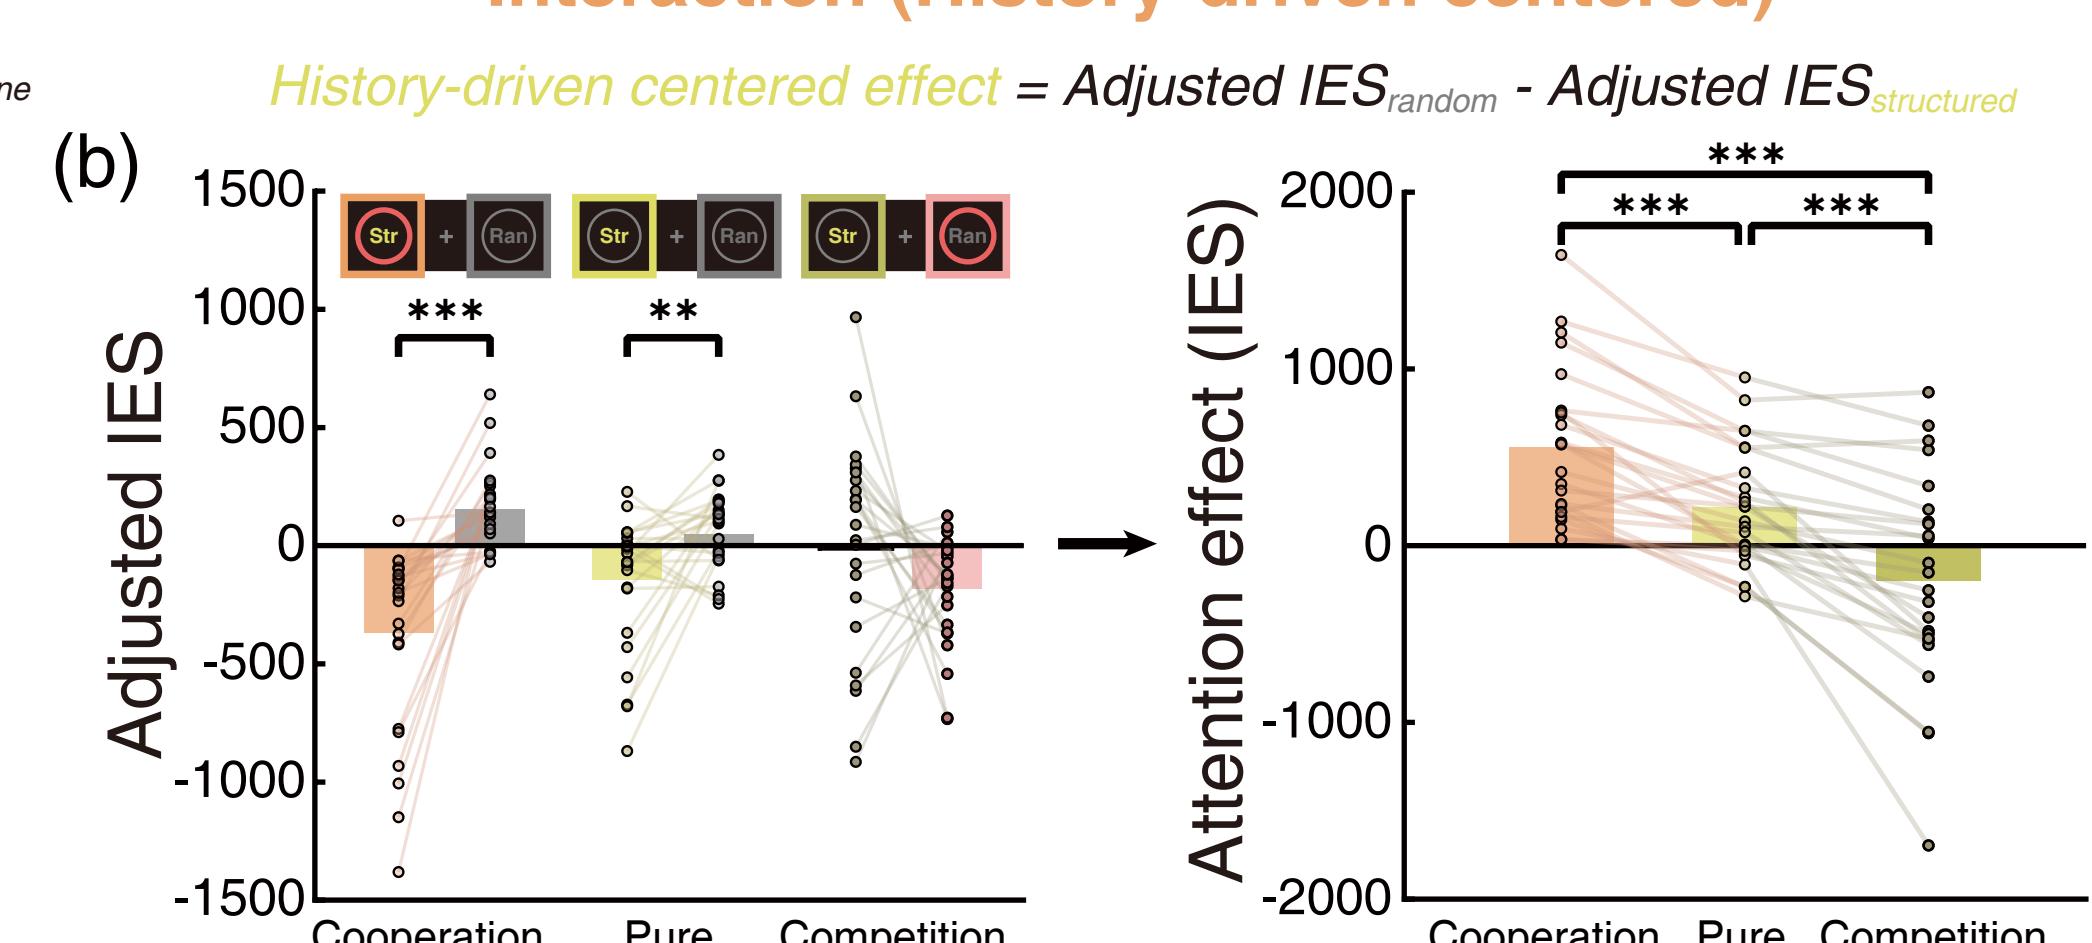

Results

Experiment 1a

History-driven

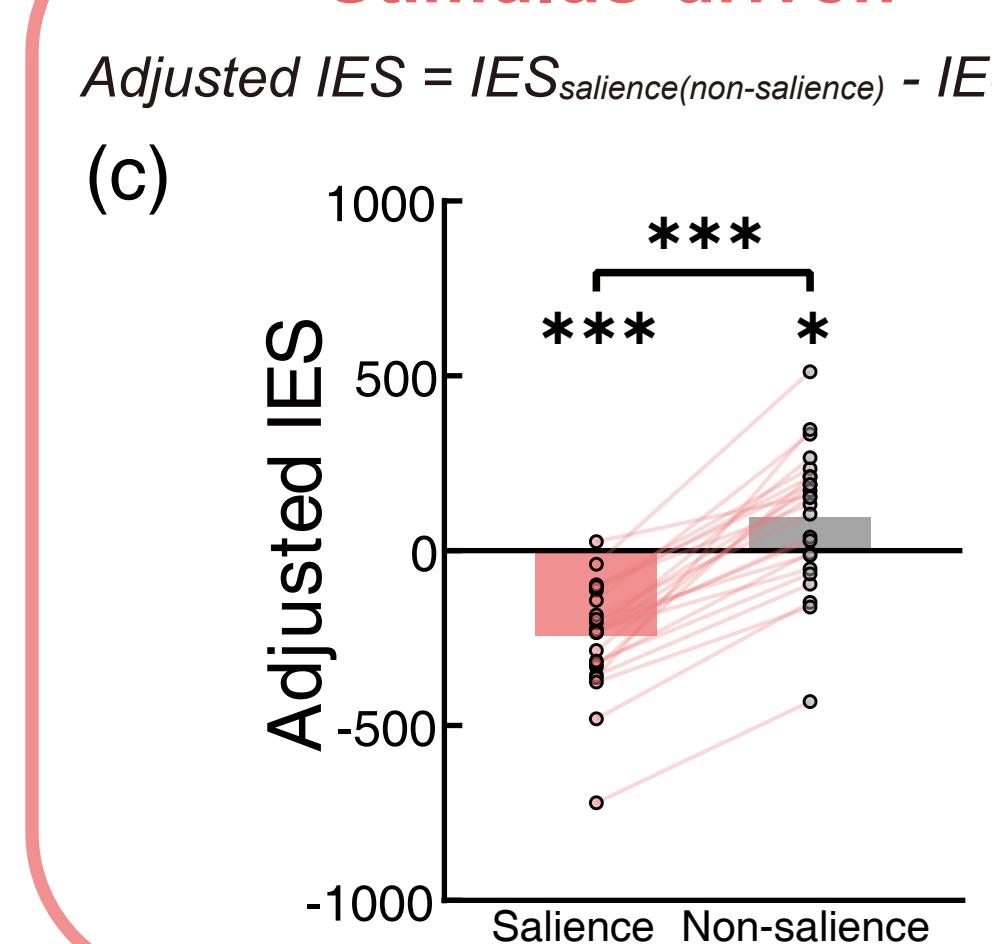

Interaction (History-driven centered)

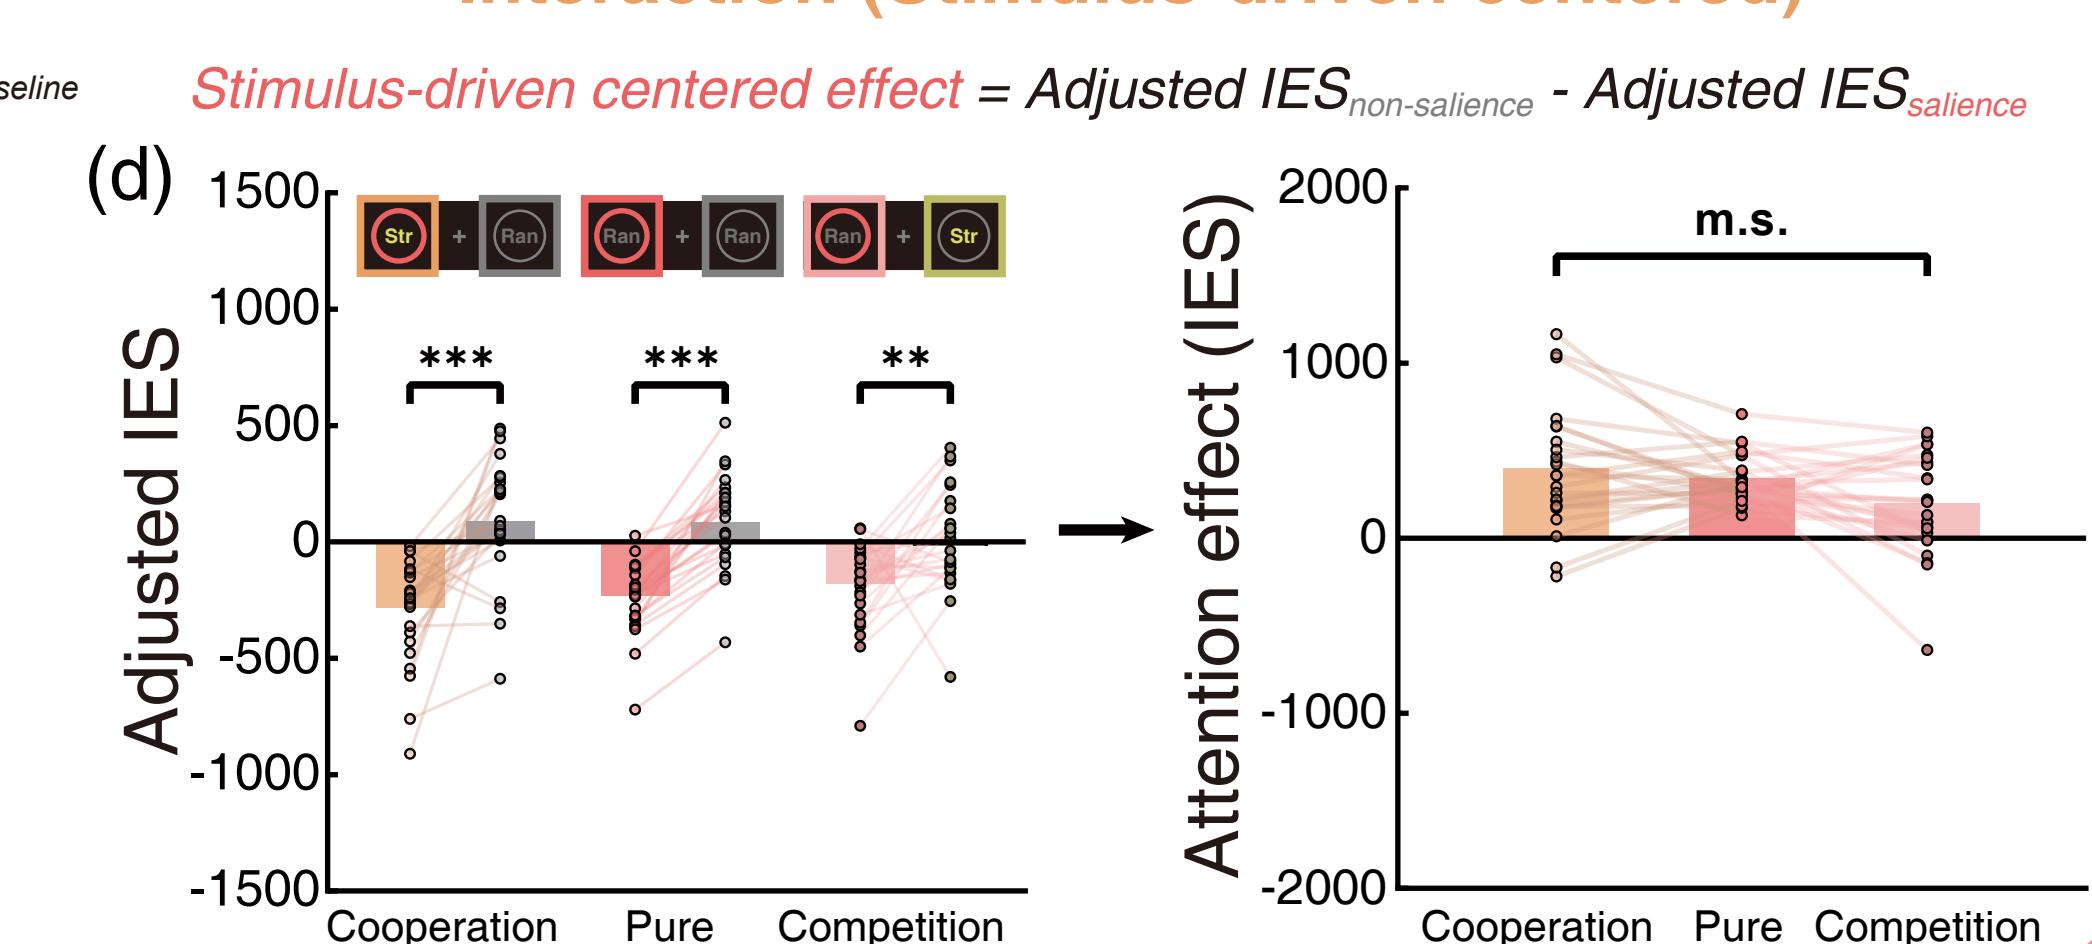

Experiment 1b

Stimulus-driven

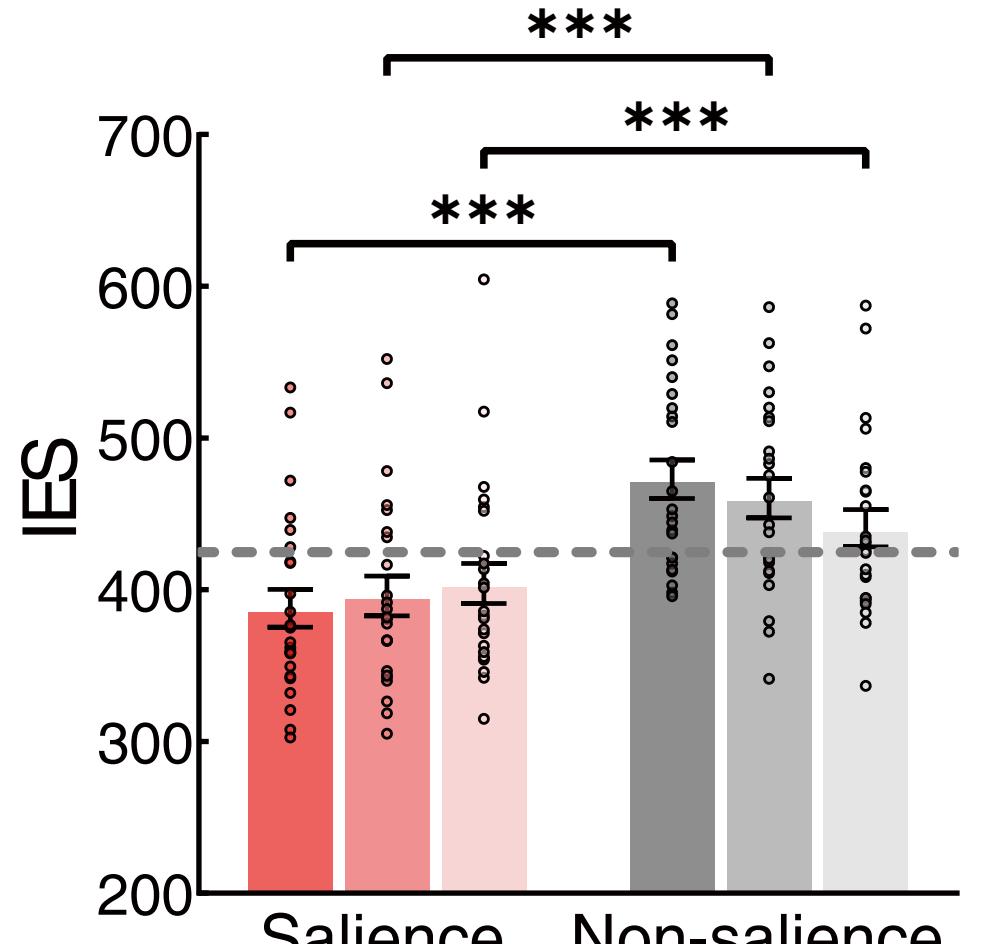

Interaction (Stimulus-driven centered)

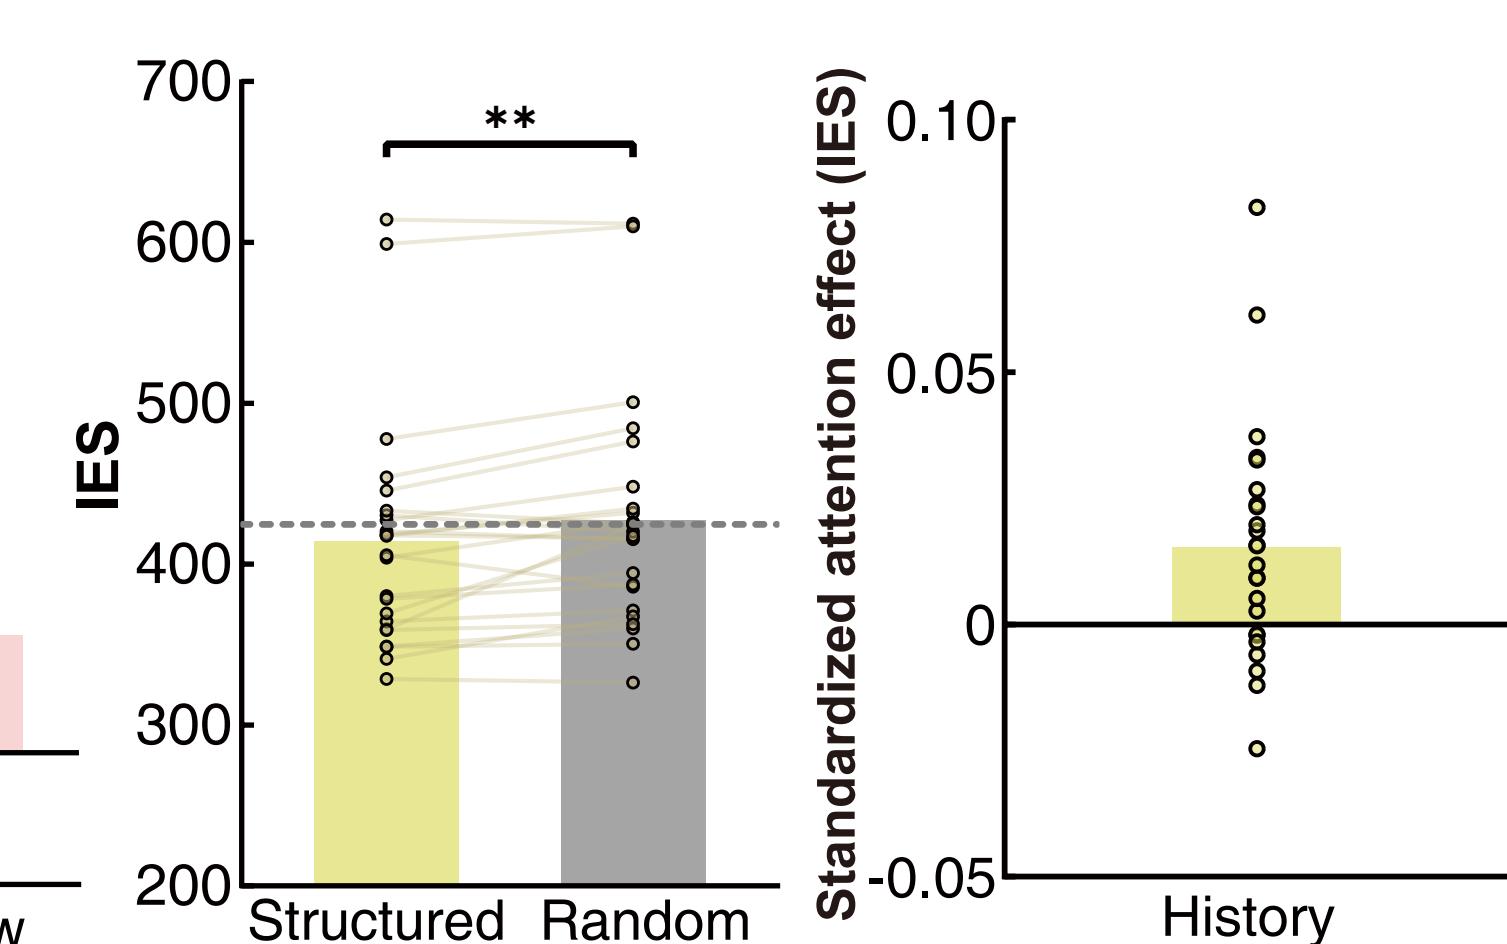

- When operating separately, both regularity and cue salience elicited prioritized attention selection.
- When the two factors coexisted, they exhibited mutual yet asymmetric impacts:
The attention effect was augmented during cooperation but diminished during competition, where history-driven selection exerted a weaker influence than stimulus-driven selection.

Experiment 2

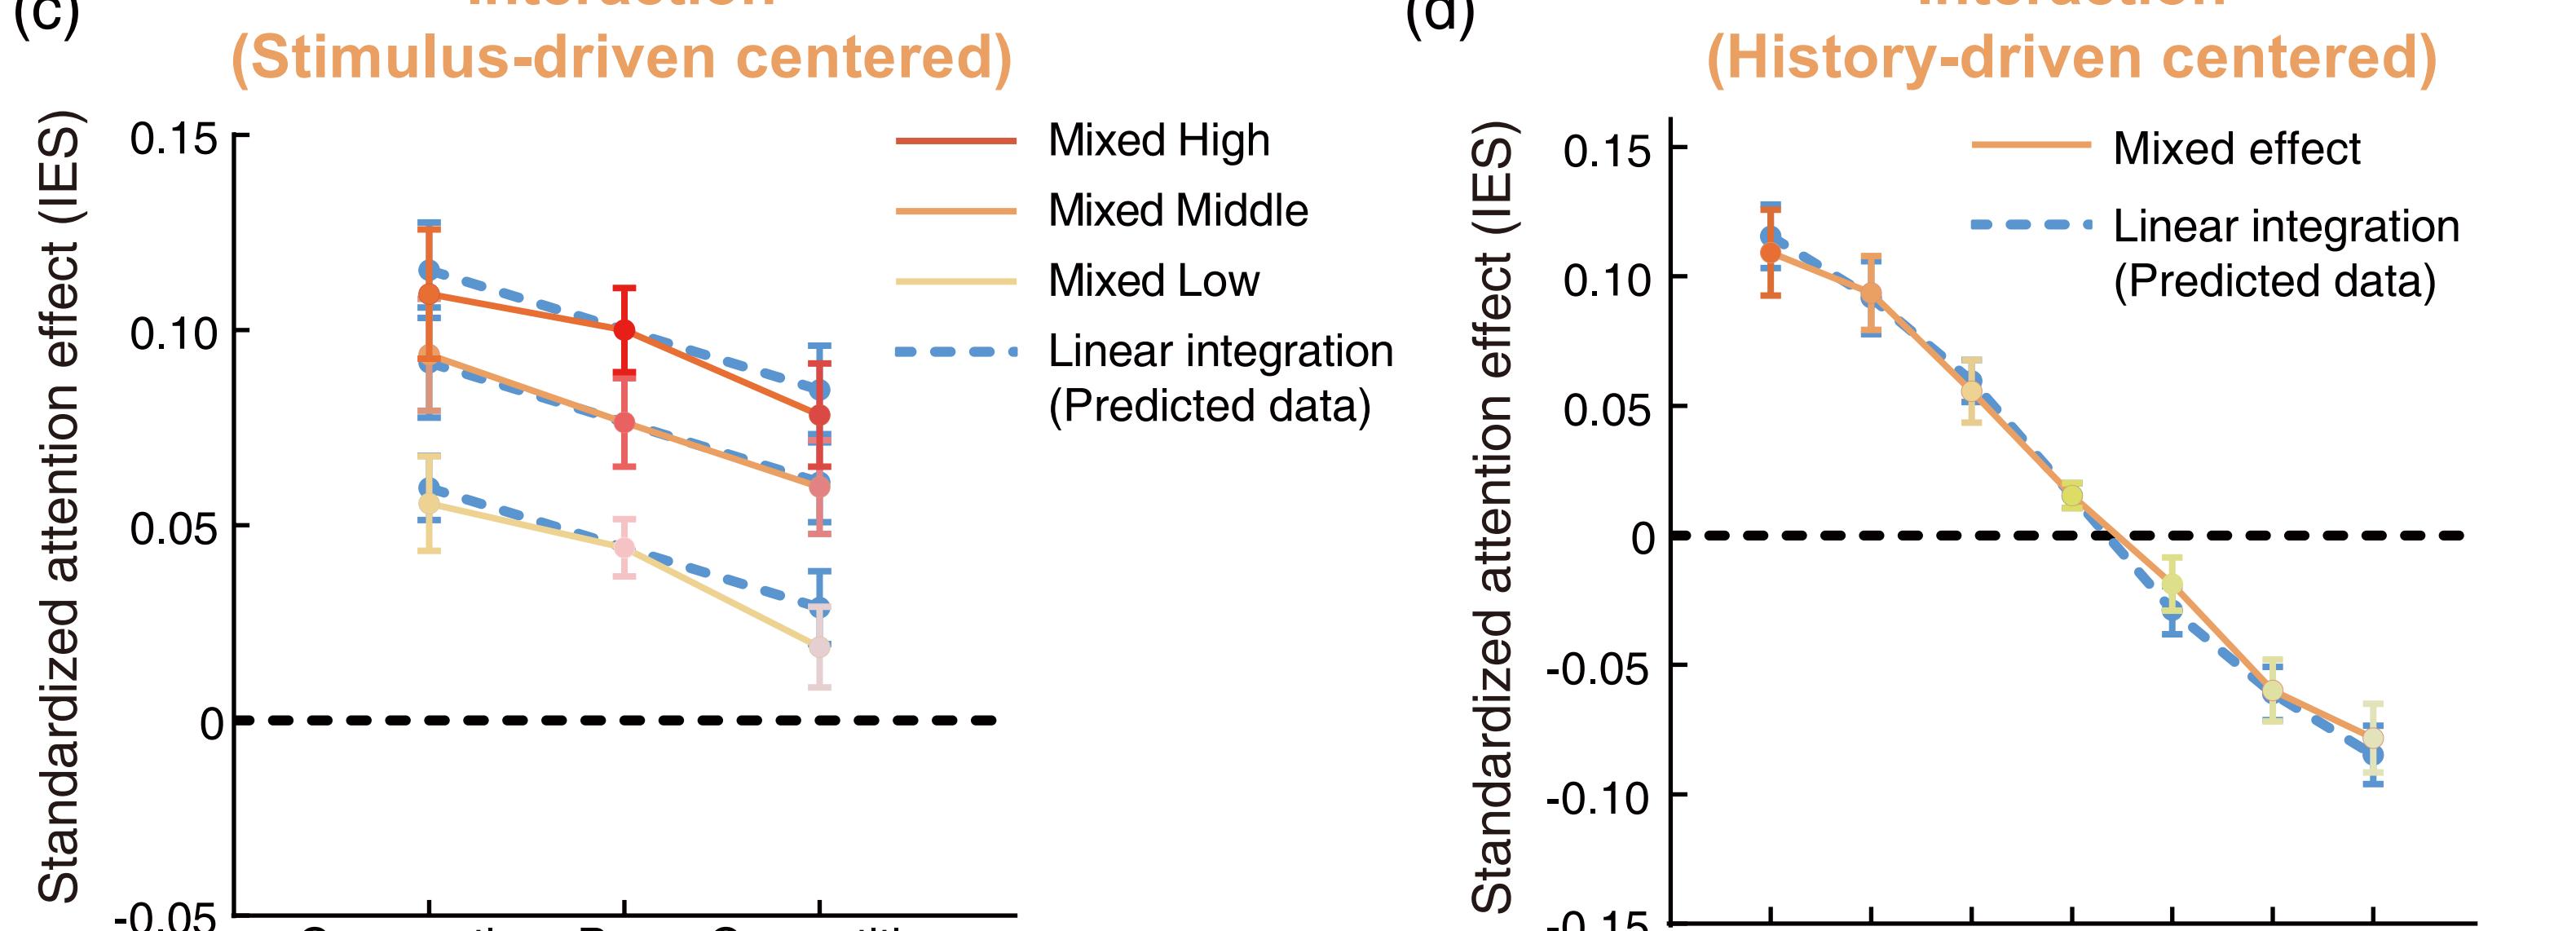

Stimulus-driven

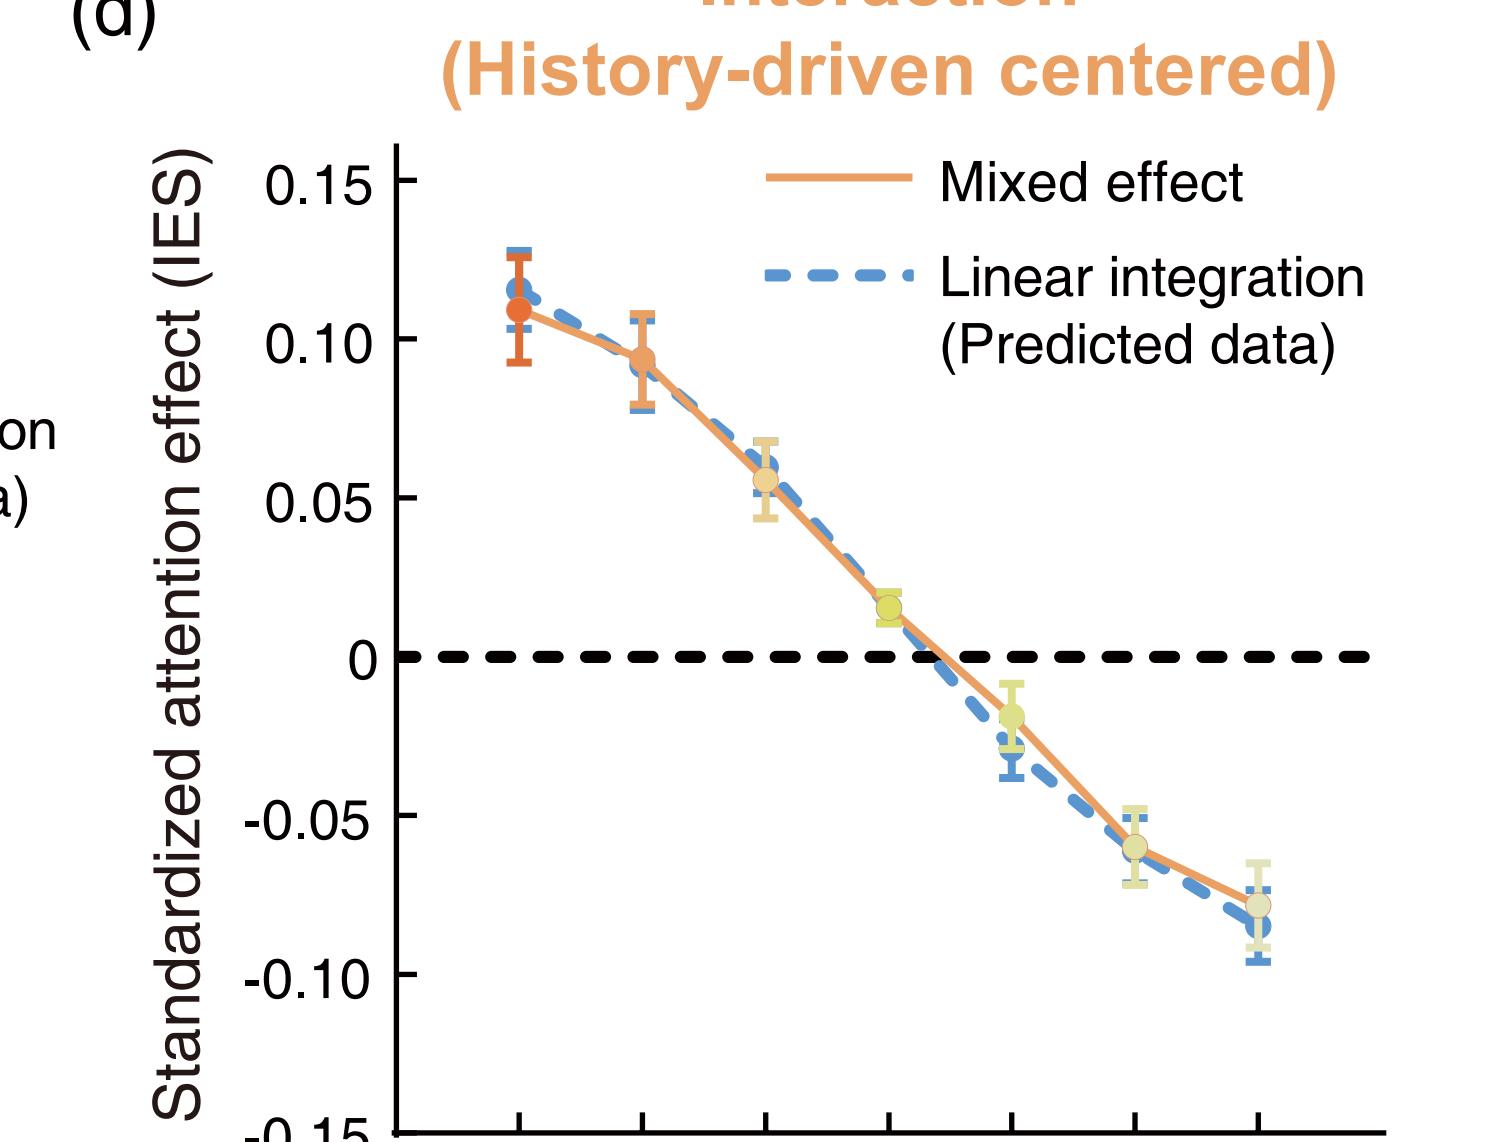

History-driven

Interaction (Stimulus-driven centered)

Interaction (History-driven centered)

- History- and stimulus-driven selections jointly shape attention priority without being modulated by the level of stimulus salience.
- The mixed attention effects in the cooperation/competition condition can be predicted by the linear combinations (sum/difference) of the two observed attention effects.
